54 Data communication process and apparatus therefor.

57 There is disclosed a process for transmitting mixed data, composed of character code data and bit image data in blocks and an apparatus therefor. Efficient transmission can be achieved by selecting the size of blocks suitably according to the quantity of data in each block or the number of blocks.

1 TITLE OF THE INVENTION

Data Communication Process and Apparatus Therefor

BACKGROUND OF THE INVENTION

5 Field of the Invention

The present invention relates to a process for data transmission and an apparatus therefor, and in particular to those for transmitting mixed data.

Related Background Art

10 For transmitting mixed data of different kinds, such as character code data and bit image data, there is already proposed a process of dividing a text into a plurality of character code blocks and bit image block, and transmitting the blocks in succession.

15 However, in case many characters, photographs and pictures are mixedly present, there will be involved a large number of blocks, which require a complicated protocol in transmission and a long time for reconstruction of the text upon reception, thus leading to a deteriorated
20 efficiency of transmission.

SUMMARY OF THE INVENTION

In consideration of the foregoing, an object of the present invention is to provide a process for trans-
25 mitting mixed data.

Another object of the present invention is to provide a process for transmitting mixed data with a high

1 transmission efficiency.

Still another object of the present invention is to provide an efficient process for transmitting a document containing areas where characters and non-character
5 images are overlapped.

Still another object of the present invention is to provide a process of transmission allowing easy reproduction of the original document from mixed data.

Still another object of the present invention
10 is to provide a data transmission process for transmitting a document by suitably dividing the same into blocks.

Still another object of the present invention is to provide a data transmission process for transmitting a document by dividing the same into a limited number
15 of blocks.

Still another object of the present invention is to provide a data transmission system capable of transmitting, in mixed manner, data obtained by word processing and data obtained by image processing.

20 Still another object of the present invention is to provide a communication terminal apparatus enabling efficient processing of mixed data.

Still another object of the present invention is to provide a data transmission process capable of
25 transmitting data obtained by character recognition.

The foregoing and still other objects of the present invention will become fully apparent from the following description.

1 BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 is a block diagram of a communication terminal apparatus employing a transmission process of the present invention;

5 Fig. 2 is a perspective view of a communication apparatus embodying the present invention;

Figs. 3, 4A to 4C, 6, 7A to 7E and 9 are views showing data formats; and

10 Figs. 5, 8A, 8B and 10 are flow charts showing a transmitting process.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

Fig. 1 is a block diagram of an embodiment of the present invention, and Fig. 2 is a perspective view of the embodiment.

A reader 10 is provided to generate an electrical signal by reading an original document.

A facsimile apparatus 20 is provided with a reader/printer interface 21; an image compression unit (ICU) 22; a program memory (PMEM) 23; a bit move unit (BMU) 24; an image memory (IMEM) 25; a video random access memory (VRAM); a central processing unit (CPU) 27; a communication interface 28; a bus 29; and a communication control unit (CCU) 30.

25 The image compression unit (ICU) 22 is provided for compressing or expanding data, and employs a two-dimensional compression (high compression) for

1 increasing the encoding rate.

The program memory (PMEM) 23 is provided with memory areas for an operation system program and an application program for controlling input/output devices
5 and various units of the facsimile apparatus 20, for a font memory for converting character code data into image bit data, and for storing and editing text code data or character data obtained by key entry or word processing.

The program memory (PMEM) 23 is provided with
10 a memory management unit (MMEU) and a work area functioning as a buffer for transmitting data from a rigid disk 50 through the communication control unit (CCU) 30 or receiving data from the unit 30 to the rigid disk 50 and for transmission speed matching between the rigid disk
15 and the communication channel.

The bit move unit (BMU) 24 is provided for image processing such as enlargement, reduction, rotation, displacement or extraction of a predetermined image in bit unit on a cathode ray tube 60.

20 The image memory (IMEM) 25 has a capacity of 4 Mbytes for storing image data from the reader, edited image data obtained from the bit move unit 24, or bit data (for example of 1 bit per pixel) converted into an image from text code data, mixed data or character code
25 data obtained by key entry or word processing. The mixed data include both bit image data and character code data in a page. These data are divided into image blocks

1 and character blocks, each of which is given an identification code for administration and storage. The image memory 25 is also utilized as a buffer for temporarily storing predetermined data, thereby matching the speed of the reader 10, printer 70 and communication channel 40.

The video random access memory (VRAM) 26 is provided for storing image data to be displayed on the cathode ray tube 60 by a bit map data for example of a 10 bit per pixel.

As non-volatile external memories there are provided a rigid (hard) disk memory 50 and a floppy disk memory 51, which may be replaced by another non-volatile backup memory, for storing data to be transmitted or data 15 received.

A keyboard 61 is provided for entering command data for transmission or reception, command data for word processing or image processing, and character data for word processing.

20 A pointing device 62 is used for moving a cursor image on the cathode ray tube 60; thus designating a position for image processing etc. Also the device 62 is used for block designation of mixed data. Coordinates indicating the blocks are stored and administered by the program memory (PMEM) and treated as a part of identification code data or header at data transmission. 25

For high-speed transmission of a large amount

1 of image data with a high resolving power (density), the
communication channel 40 is preferably composed of a digital
channel, for example a digital data network or a digital
data packet network, of for example 64 Kbit/sec.

5 The printer 70 is composed of a laser beam printer
capable of data printing at a rate of 3 Mbps.

Fig. 3 shows a page of mixed data divided into
blocks 1 - 8, corresponding to the display frame of a
page on the cathode ray tube 60, to the data of one page
10 at data transmission, or to the print sheet of a page
at the printing of received data. In case of preparing
such mixed data of plural pages, storing the same in the
rigid disk 50 and transmitting the data at a time, header
data 1 - n are attached in front of block data 1 - n as
15 shown in Fig. 4, and each header indicates whether succeed-
ing block data are image data or character data, the size
of the block data, and the position thereof in a page.
Signal A is an acknowledge signal for transmission or
reception of block data, and a signal EOP is emitted when
20 the transmission of a page is completed.

Data of a page of the original from the reader
10 are stored in the image memory 25, then transferred
to the VRAM 26 and displayed on the cathode ray tube 60.
The image thus displayed is trimmed, through the bit move
25 unit 24 according to editing instructions given by the
keyboard 61 or the pointing device 62, to obtain an image
corresponding to a block 3, which is again stored in the

1 memory 25.

Text code data from the keyboard 61 are stored in the memory 23, then converted into bit data, transferred to the VRAM 26 and displayed, as a text of one
5 page, on the cathode ray tube 60. The data are edited in the same manner as the image processing to obtain character data corresponding to blocks 1 - 6 shown in Fig. 3, and again stored in the memory 23, in the form of codes. Position data of each block are controlled,
10 together with the attribute of data, in the memory 23. Then, in response to a next command, image data and position data of the blocks 7, 8 of the memory 25 are read and displayed, through the VRAM, in the position of the block 3 on the cathode ray tube 60, thus finally providing a
15 display of blocks 1 - 8 shown in Fig. 3. These mixed data are read from the memories 23, 25 in the order of blocks 1 - 8 and are stored in the rigid disk 50.

Fig. 3(c) shows an example of the document of a page after editing, wherein blocks 1 to 6 are character
20 code blocks, and blocks 7, 8 are bit image blocks.

Thus there is required a large number of blocks in transmission if character code blocks and bit image blocks are mixed in the document.

These blocks can however be converted into two
25 blocks 9, 10 as shown in Figs. 3(a) and 3(b).

Fig. 3(a) shows the code block 9, in which an area corresponding to the block 7 need not be filled

1 with codes since it is positioned at the end of lines,
but, in an area corresponding to the block 8, spaces
between character codes are filled in with blank codes
such as space or tabulator codes.

5 Fig. 3(b) shows the bit image block 10 which is
selected as a smallest rectangular block at least
including the blocks 7 and 8, but there may be employed
any rectangular block without limitation in size. An
area corresponding to the character code block shown in
10 Fig. 3(c) is totally filled with white bits.

Fig. 5 is a flow chart for block conversion.
At first a document as shown in Fig. 3(c) is obtained
by combining the bit image data from the reader 10 and
the code data from the keyboard 61 on the cathode ray tube
15 60 through a process as explained before, and there are
entered a code indicating the boundary of block (for
example indicating a starting coordinate of the block
and the dimension thereof) and an attribute code indicating
the nature of the block. Then there is discriminated,
20 from the attribute code, whether a character code block
is present (2), then, if present, there is discriminated
whether plural blocks are present (3), and, if plural
blocks are present, the block area 8 between such plural
blocks is filled with space codes (4). The block 7 need
25 not be filled with the space codes because return codes
are present at the boundary with the block 2. Then a
block consisting solely of character codes is obtained

1 by deleting such codes indicating the block boundary and
changing the attribute of the block and is stored in the
PMEM (5).

Subsequently there is discriminated where a bit
5 image block is present (6), then, if present, there is
discriminated whether plural blocks are present (7), and,
if plural blocks are present, the space between the blocks
is filled with white bits (8). Subsequently the attribute
of the block is changed by deleting the codes indicating
10 the boundary of the blocks, and a block consisting solely
of bit images is stored in the IMEM (9). Then there is
discriminated whether plural blocks are present in total
(10). As there are the character code block 9 and image
block 10 in this case, an overlapping attribute code is
15 set in the PMEM, instructing to overlay these blocks,
taking a point A of the block 9 as the reference. Then,
in response to the entry of a transmission instruction,
there are emitted, in succession, said overlapping
attribute code, code data and bit image data respectively
20 stored in the PMEM and IMEM. The attribute code may be
transmitted after the transmission of the document data.

At the receiving side, the transmitted data of
blocks 9, 10 are stored in the disk 50, and transferred
to the PMEM and IMEM. Then the overlapping attribute
25 code transmitted before or after the data reception,
then the data of the block 9 are converted into bit
image data by a character generator, while the encoded

1 data of the block 10 are decoded into bit image data by
a decoder, and the data of these blocks are superposed
with the point A as the reference to reproduce the
transmitted next shown in Fig. 3(c), on the cathode
5 ray tube 60 or on the printer 70.

Fig. 6(c) shows a document which contains,
between character code blocks 11 and 13, a block 12 in
which character codes and bit image data are overlapped.
The block 12 can be divided, for transmission, into a
10 code block 12-1 and a bit image block 12-2 of a same
size. In this case there will be required four blocks,
but a higher efficiency of transmission can be attained
in comparison with a case of further dividing the block
12 into overlapped blocks and non-overlapped blocks. In
15 this case an overlapping attribute code is attached to
the block 12 while the boundary and attribute thereof
are retained, and, at the receiving side, the original
text is regenerated by superposing the transmitted blocks
12-1, 12-2 only.

20

25

1 Fig. 6(a) and 6(b) show two blocks, i.e. a
character code block 14 and a bit image block 15
constituting one page of the text (c) including an
overlapped block. Also in this case, as explained
5 before, the boundary of the blocks is eliminated, then
an overlapping attribute code, indicating an overlay
with a reference point B, is given, and transmission
is effected. At the receiving side, the data of the
blocks 14, 15 are synthesized according to the attribute
10 code, and the text thus obtained is displayed or printed.

It is also possible to develop the code block
12-1 of the overlapping block 12 into bit image data in
the program memory PMEM, then overlaying the data with
the bit image data of the image block 12-2 and storing
15 thus obtained image pattern (c) into the image memory
IMEM. In this case there are required only three blocks
11, 12, 13 because the boundary and attribute of the
code block 12-1 are eliminated, so that a higher trans-
mission efficiency can be attained. The boundary and
20 attribute of the block 12 are same as those of the bit
image block 12-2. The boundary position and attribute
code of the blocks 11 - 13 are contained in the headers
C, I of the blocks shown in Fig. 4.

In the following there will be explained optimum
25 division of transmitting blocks. Figs. 7A to 7E
illustrate examples of division of a text of one page
containing a character code data area C and an image

1 data area I.

In the example shown in Fig. 7A, the character code area is divided into blocks C1, C2 while the image area is taken as a block I1, without transparent overlapping. In this case the transmission is effected in three blocks C1, C2 and I1. The starting points and sizes of the blocks can be defined by the coordinates of the points P1 and P2.

In the example shown in Fig. 7B, a character code block C'1 and an image block I1 are subjected to transparent overlapping. In the block C'1, an area outside C1 have no character code data, but the return codes at the ends of character rows of the area C1. In this case the transmission is conducted in three blocks C'1, C2 and I1.

In the example shown in Fig. 7C, the character areas C1, C2 are unified as a one-page block CA which is subjected to transparent overlapping with the image area I1. In this case the transmission is conducted by a page CA and a block I1.

In the example shown in Fig. 7D, the character area C1, C2 and the image area I1 are respectively unified as pages CA and IA which are subjected to transparent overlapping. In this case the transmission is conducted in two pages. The transmission efficiencies in these examples are variable, but, in the present example where characters represent a considerable area,

1 a transmission with a page of character codes and a
block of image shown in Fig. 7C is estimated efficient
because the header codes for the blocks C1, C2 can be
dispensed with.

5 The example shown in Fig. 7D also does not
require header codes of the blocks, but during image
formation IA, an area outside the area I1 has to be filled
with uniform white or black data, which increases the
amount of information even when compressed. Consequently
10 this case is considered disadvantageous.

However, if two blocks I1, I2 almost occupy a
page as shown in Fig. 7E, there may become advantageous
the two-page transmission shown in Fig. 7D, wherein I1
and I2 are considered as a group 1 and C1 to C3 are
15 considered as a group 2.

In this manner the selection of division becomes
different according to the nature and distribution of
the information.

In order to identify an optimum division the
20 total amounts of data in various divisions are calculated
and compared, and the transmission is conducted according
a method of division giving a minimum amount of infor-
mation.

Fig. 8 shows a flow chart of a procedure for
25 such identification.

At first a step S-0 sets "4" as the number n of
division of one-page data corresponding to a frame of

1 the cathode ray tube as shown in Fig. 7. A step S-1
effects an area division shown in Fig. 7A, and determines
the amounts of data C_{1m} , C_{2m} respectively corresponding
to the code data of the block C1 and those of the block
5 C2 in the program memory PMEM, according to the position
data P1, P2 at the aforementioned text editing. The
data amounts can be obtained from the memory address to
the position P2, stored in advance in the memory PMEM.
Then a step S-2 compresses the bit data corresponding
10 to the block I1 in the image memory IMEM by means of
the ICU 22 to obtain the compressed data amount I_{1m} .
Then the total amount of data $M1 = C_{1m} + C_{2m} + I_{1m}$ is
determined and stored in the program memory PMEM. The
compressed data are temporarily stored in the rigid
15 disk 50.

Subsequently the program returns to the step
S-1 to effect the division of Fig. 7B, thus determining
the amount of data corresponding to the block C'1. In
this case the amount is almost same as that of the block
20 C1 shown in Fig. 7A. The obtained amount of data is $M2$
in this case.

Then there is effected the division shown in
Fig. 7C to obtain the data amount corresponding to the
block CA, with the total data amount $M3$.

25 Then there is effected the division shown in
Fig. 7D to obtain the data amount corresponding to the
block IA. In the block, the amount of data is obtained

1 by adding, to I_{lm} , the amount of data obtained by
compressing white bits outside the block I_l . The total
data amount in this case is M_4 .

The number n of divisions is already set as 4.

5 A step S-3 effects a decrement from the number n for
each calculation of the total data amount, and a step
S-4 discriminates whether the number has reached zero.
Then a step S-5 compares the total amounts of data $M_1 -$
 M_4 to determine the dividing mode giving the minimum
10 data amount.

Subsequently the page data are divided according
to thus determined dividing mode and are stored in the
rigid disk, and thus divided blocks are transmitted in
succession in response to the transmission command.

15 In the foregoing explanation the dividing mode
is determined according to the total amount of data,
but, if the total amount of data does not vary
significantly as in the cases shown in Figs. 7B and 7C,
the mode is preferably determined according to the
20 number of blocks since the transmission of two blocks
may be more advantageous in efficiency than the trans-
mission of three blocks. The number of blocks is stored
for each of the divisions shown in Figs. 7A to 7D. It
is also possible to achieve block division by manually
25 selecting one of such dividing modes.

In the foregoing there has been explained a
mode of determining an appropriate division in response

1 to a transmission command and automatically effecting
transmission upon completion of the division, but it
is also possible to effect an appropriate division in
response to a preliminary command, then to provide a
5 display of the appropriate division and to effect
transmission in response to a transmission command
given thereafter.

Also as another embodiment it is possible to
normally effect a standard block division as shown in
10 Fig. 7A, but, in case the number of blocks exceeds a
predetermined maximum number, for example 31, to forcedly
select a dividing mode in which the number of blocks
becomes less than the maximum level. In such case a
discrimination is made as to whether the number of
15 blocks exceeds a maximum number MAX as shown in Fig.
8B, and, if the maximum number is exceeded, a flow chart
shown in Fig. 8A is executed to determine an optimum
dividing mode from the amounts of information in various
dividing modes not exceeding the maximum number. In
20 this manner the time required for preliminary process
prior to transmission can be shortened.

In the following there will be explained an
embodiment provided with a character recognizing
function in addition to the above-explained functions.

25 Also in this embodiment the structure is same
as that shown in Fig. 1. Data of an original text
read by the reader 10 are stored in the image memory 25,

1 then subjected to character recognition by the CPU 27
and a corresponding code is allotted to each recognized
character. The character recognition can be conducted
by an already known process. In such character
5 recognition of the original, certain characters may
remain unrecognizable. There will be required a large
number of blocks if such unrecognized characters are
transmitted as image data of respectively different
blocks. In the present embodiment, therefore, the
10 recognized characters are transmitted as code block as
shown in Fig. 3, while the unrecognized characters are
transmitted as a bit image block, and both are overlaid
at the receiving side.

Fig. 9 shows an example of the fourth embodiment.
15 In the character recognition of an original text shown
in Fig. 9(a), it is assumed that two groups of characters
remain unrecognized. In the code block shown in Fig.
9(b), blank codes are given to the unrecognized
characters.

20 Fig. 10 is a flow chart showing the control
procedure of the CPU 27 in the fourth embodiment.

Now referring to Fig. 10, a step S1 causes the
CPU 27 to store the bit image data of the original
text, read by the reader 10, into the image memory 25.
25 Succeeding steps S2 - S6 effect character recognition
character by character. In the character recognition,
the bit image data stored in the image memory 25 are

1 at first scanned to recognize a character row, and, upon
completion of the recognition, each character column is
recognized. In this manner the bit image data of the
original text are divided into rows and columns of
5 characters, and each character is then recognized.
However the character recognition is not necessarily
limited to the process of the present embodiment but
may be conducted in various methods.

Steps S-2 and S-3 effect recognition of a charac-
10 ter, and a step S-4 stores a corresponding character code
into a code block area of the program memory 23 if the
character is recognized, or, if the character is un-
recognized, stores a space code in the code block area
and the bit image data of the unrecognized character in
15 a bit image preparation area of the memory 23, at an
address of the unrecognized character. The program
memory (PMEM) 23 is provided with a code block area, a
bit image preparation area, and a bit image block area.
The code block area and the bit image prepara-
20 tion area are respectively provided with addresses of a
number of divisions for character recognition (character
rows x character columns). The bit image of a character
to be recognized is given size information (a, b) of
the character bit image block as shown in Fig. 9(c).

25 When a succeeding step S-6 identifies the
completion of recognition of all the characters, a step
S-7 discriminates the presence of unrecognizable
characters.

1 If the step S-7 identifies the absence of such
unrecognizable characters, a step S-8 attaches in-
formation of address and size of the code block, for
example (x, y) and (x', y') shown in Fig. 9(b), infor-
5 mation indicating the arrangement of characters and
identification data indicating a code block, in front
of the data of the code block area in the program memory
23, and the transmission is conducted as code block
data.

10 On the other hand, if the step S-7 identifies
the presence of unrecognizable characters, steps S-9
to S-12 read the minimum address $x_{\min} = x_1$, $y_{\min} = y_1$,
and the maximum address $x_{\max} = x_n$, $y_{\max} = y_n$ (see
Fig. 9(c)) of the bit image data of the unrecognizable
15 characters in the bit image preparation area of the
program memory 23, and steps S-13 to S-15 prepare a bit
image block. At first the step S-13 sets the address
of the starting point (x_{\min}, y_{\min}) of the bit image
block and the size information $(x_{\max} + a - x_{\min}, y_{\max} + b - y_{\min})$,
20 and the step S-14 sets identification information
indicating that the block is bit image data and an
overlap attribute indicating that the block is to be
overlapped with the code block. Then the step S-15
stores the bit image data of the bit image preparation
25 area respectively in the areas of unrecognizable
characters in the bit image block area, thus obtaining
bit image data as shown in the bit image block in

1 Fig. 9(c).

The bit image data thus prepared in the step S-15 are stored as bit image block data in the program memory 23, together with the information set in the steps S-13 and S-14. In this operation, the bit image data may be encoded by the ICU 22.

Then a step S-16 adds, to the code data in the code block area, address information and size information of the code block, identification information and information indicating the arrangement of characters, then stores thus obtained code block data in the program memory 23, and transmits the code block and the bit image block to the destination.

As explained in the foregoing, the fourth embodiment effects encoding of characters by character recognition, and is therefore capable of saving manpower in comparison with the character input through the keyboard 61, thus reducing the time required for communication. Besides the unrecognized characters are transmitted in bit image data to achieve secure transmission of the original data. Furthermore the recognized characters and unrecognized characters are respectively transmitted in a code block and a bit image block, so that the number of block is reduced in comparison with the case of dividing the data into plural blocks. In addition the data communication time is therefore reduced and the data processing at the

1 transmitting and receiving sides is simplified.
Furthermore, the above-mentioned code block obtained
by character recognition may include code data of a
text prepared by a word processor.

5 Examples of different data include graphic code
data, character code data, line image bit data, halftone
image data etc.

10

15

20

25

1 WHAT WE CLAIMED IS:

 1. A data communication process for transmitting
two or more data in mixed manner, which comprises
transmitting said data in appropriately divided data
5 blocks.

 2. A data communication process according to
Claim 1, wherein said appropriate division is determined
according to the amount of data of the blocks.

10 3. A data communication process according to
Claim 1, wherein said appropriate division is determined
according to the number of divisions.

15 4. A data communication process according to
Claim 1, wherein said division into blocks is determined
by arbitrarily selecting one of dividing modes.

20 5. A data communication process for transmitting
and/or receiving character codes and bit images, which
comprises transmitting separately a first block
composed of character codes, a second block composed
of bit images and a third block composed of data in
which character codes and bit images are overlapped.

25 6. A data communication process according to
Claim 1, wherein transmission is conducted after

1 elimination of the boundary between the third block and
the first or second block.

7. A communication terminal apparatus for
5 transmitting and/or receiving character codes and bit
images, which comprises transmitting or receiving
information, composed of respectively plural blocks of
character code blocks and bit image blocks, by constitut-
ing a page with blocks of a number less than the number
10 of above-mentioned blocks.

8. A data transmission process for transmitting
two or more data in mixed manner, which comprises reading
and converting information into first and second data
15 and transmitting thus obtained blocks.

(71) Applicant: **CANON KABUSHIKI KAISHA**
30-2, 3-chome, Shimomaruko
Ohta-ku Tokyo(JP)

(72) Inventor: **Abe, Shintaro**
218-6 Takakura
Fujisawa-shi Kanagawa-ken(JP)

(72) Inventor: **Okada, Naoyuki**
1428-4 Nakada-cho Totsuka-ku
Yokohama-shi Kanagawa-ken(JP)

(72) Inventor: **Adachi, Muneo**
17-3 Hino Minami 1-chome Konan-ku
Yokohama-shi Kanagawa-ken(JP)

(72) Inventor: **Shimamura, Yasuhito**
41-1 Mikakedai Midori-ku
Yokohama-shi Kanagawa-ken(JP)

(74) Representative: **Beresford, Keith Denis Lewis et al,**
BERESFORD & Co. 2-5 Warwick Court High Holborn
London WC1R 5DJ(GB)

(54) **Data communication process and apparatus therefor.**

(57) There is disclosed a process for transmitting mixed data, composed of character code data and bit image data in blocks and an apparatus therefor. Efficient transmission can be achieved by selecting the size of blocks suitably according to the quantity of data in each block or the number of blocks.
